Abstract

Introduction: Ewing's sarcoma is a rare and aggressive type of cancer that affects bone
or soft tissues. It originates from precursor cells of bone tissue or the peripheral nervous
system, with its incidence peaking during the second decade of life. It is most commonly
found in long bones but can, rarely, affect the head and neck region. **Case Report:** This
case involves a 13-year-old female adolescent who initially presented with left-sided
otalgia and developed subsequently ipsilateral peripheral facial paralysis. Subsequent
diagnosis revealed a primary Ewing's sarcoma of the temporal bone. **Discussion:** The
discussion covers the disease progression, its clinical and pathological characteristics, as
as well as the diagnostic and therapeutic methods applied in this case. **Conclusions:** This is
an extremely rare case of Ewing's sarcoma of the temporal bone with distant metastases.
The progression of this case highlights the need for constant vigilance and the
consideration of the potential for distant spread, guiding the establishment of

1. Introduction

Ewing's sarcoma, a histopathological subtype of sarcoma composed of small
Round cell carcinoma, which frequently affects the long bones of the limbs and trunk, was first
described by James Ewing in 1921. It is much more commonly observed in
Caucasian children and adolescents, and somewhat more common in individuals of
It is more common in males and is generally diagnosed in the second decade of life. Among the
which are located in the skull, an extremely small percentage may be
develop in the temporal bone, usually involving the frontal, parietal or
ethmoid 2.

A complex case of primary Ewing's sarcoma of the temporal bone is presented, with
Intracranial extension, affecting a 13-year-old female adolescent.
age, focusing on clinical manifestations, diagnostic challenges faced, and
a multidisciplinary approach, which was essential for the formulation of a plan.
appropriate therapy. The finding of distant metastasis shows that
This is an atypical presentation of the disease, as there is only one case described in the literature with
a similar evolution. The study was approved by the Ethics Committee and
Research (CEP) with CAEE no. 71314223.9.3001.5042 and is linked to the Hospital
Albert Sabin Children's Hospital – CE.

2. Case Report

A 13-year-old female adolescent presented with a history of left-sided otalgia.
associated with pain in the ipsilateral mandibular region, initially with partial relief after
use of nonsteroidal anti-inflammatory drugs, in addition to sporadic episodes of vertigo
Rotational pain and nausea. Over three months, it progressed to left-sided peripheral facial paralysis.
ipsilateral progressive hearing loss, mild dysarthria, intermittent liquid dysphagia,
She reported bloody otorrhea and a significant worsening of pain intensity, which led her to...

osteolytic lesions in the right ilium and in the vertebral body of L1, which constituted lesions metastatic.

The patient has opted to begin treatment with radiotherapy and chemotherapy. She continues to be... Treatment at HIAS, with a good response to the established therapy.

3. Discussion

Although metastases of Ewing's sarcoma (ES) are generally common, there is only one Another case described in the literature involves metastatic lesions originating from a primary SE of skull, making the current report the second to demonstrate the existence of metastases to the skull. distance. In this way, there is a better prognosis when it comes to an injury. primary cranial injury, when compared to primary injuries in other parts of the body 3. Early diagnosis is of utmost importance, as the tumor exhibits growth. Extremely fast. The radiological examination is essential to help determine the To determine the extent of the disease, as well as to define appropriate therapeutic strategies. It is possible to use Computed Tomography (CT), which offers a better evaluation of the cortical bone, in addition to allowing detailed examination of the skull base; of Nuclear Magnetic Resonance (MRI), which provides adequate analysis of soft tissues. and enables the determination of invasion of the spinal cord, orbit, and intracranial region; and of Positron Emission Tomography (PET-CT) to investigate the existence of distant metastases 4.

Despite all the resources available, the diagnosis of SE is difficult to confirm. Histopathological analysis combined with immunohistochemistry is the gold standard . 5. Characteristics Histopathological findings include small, round, monomorphic cells with cytoplasm. Sparse, round nuclei and imperceptible nucleoli. Genetic molecular analysis. highlighting the chromosomal translocation on chromosome 22q12 is pathognomonic. Overexpression of CD99, a transmembrane protein encoded by the MIC-2 gene, is another useful marker detected by immunohistochemistry 6.

Advances in multimodal therapy have considerably improved survival rates. For sarcomas in general. The treatment of intracranial SE had a good prognosis. relatively worse, when only surgery and radiotherapy were listed as options. treatment, with a survival rate of approximately 10% at 5 years. However, with the
